A one-pot reaction of NiII 1, CoII 2, FeII 3 and MnII 4 with 2,2'-bipyridine (bipy) and azide in water leads to [M(bipy)(N3)2]n chains where the metal ion is alternatively bridged by double end-on (EO) and end-to-end (EE) azido bridges; theoretical analysis of the variable-temperature magnetic susceptibility data of 1 and 4 reveals the occurrence of intrachain alternating ferro- (through EO) and antiferro-magnetic (through EE) interactions.

A safe strategy in designing alternating chains with ferro- and antiferromagnetic interactions has been proposed recently, and the first honeycomb-layered materials of formula [M(bipy)(N3)2] (M = Mn, Fe, Co; bipy = 2,2'-bipyridine) with alternating ferro- (through end-on azido, EO) and antiferromagnetic (through bischelating bipy) interactions have also been reported. Replacement of bipy by bipy (2,2'-bipyridine) yields chain compounds of formula [M(bipy)(N3)2] (M = NiII 1, CoII 2, FeII 3, MnII 4) with alternating EO and end-to-end (EE) azido bridges and exhibiting ferro- (through EO) and antiferro magnetic (EE) interactions. Here, we report the synthesis, crystal structure and preliminary magnetic study of compounds 1–3. The magnetic properties of 4, which is isosstructural with 2 and 3, were reinvestigated for the sake of comparison and the first theoretical analysis of the magnetic behaviour of 1 and 4 through a quantum spin model is also reported.

The one-dimensional compounds were obtained as polycrystalline green (1), orange (2) and red-brown (3) powders by adding an aqueous solution (25 cm3) of Na[N3]2 (2 mmol 1) or 10 mmol (2, 3) to a methanolic solution (5 cm3) containing bipy (1 mmol) and either Ni(NO3)2·6H2O (1 mmol, 1), Co(NO3)2·6H2O (1 mmol, 2) or FeCl2 (1 mmol, 3). The solid samples were filtered off and thoroughly washed with methanol and diethyl ether (yield ca. 50%). X-Ray quality polyhedral (1), arrow shaped (2) and prismatic (3) single crystals were grown by slow diffusion techniques in test, 2 or H-shaped (1) tubes.†

The structures of 1–4 are made up of alternating chains where the metal ions are alternately linked by two EO and two EE azido bridges (Fig. 1). Two nitrogen atoms of the bipy ligand complete a distorted MN6 octahedral environment around each metal atom. The EE and EO bridges are propagated within the chain with a mutual perpendicular arrangement. The values of the M(1)–N(3)–M(1a) angle is 101.5(1) 1, 100.9(1) 2 and 100.8(1) 3 in good agreement with the value of 101.0(2)° observed in the parent compound of MnII 4.5 The EE bridges adopt a chair conformation for the M(N6)=M unit. The values of the M(1)–N(6)–N(7) and N(7)–N(8)–M(1b) angles are 118.2(2) and 129.9(3)° in 1, 127.1(2) and 129.9(2)° in 2 and 126.5(2) and 131.2(1)° in 3 [131.5(5) and 127.3(5)° in 4]. The dihedral angle between the N(6)N(7)N(8)N(6a)N(7a)N(8a) and MN(6)N(8b) planes is 35.2(1) 1, 24.9(1) 2 and 23.7(1)° 3 (41.9° in 4). The intrachain metal–metal separation through EO azido is 3.248(1) 1, 3.322(1) 2 and 3.367(1) Å 3 [3.455(6) Å in 4] and that through EE azido is 5.117(2) 1, 5.279(2) 2 and 5.317(2) Å 3 [5.343(5) Å in 4]. The shortest interchain metal–metal separation is 8 Å [8.462(3) 1, 8.115(4) 2, 8.063(3) Å 3].

Magnetic susceptibility measurements (290–2 K) on polycrystalline samples of 4 (Fig. 2) are consistent with overall antiferromagnetic behaviour. Least-squares analysis of the χT of data of 45 leads to J1 = 2.5 cm−1, J2 = −6.3 cm−1 and g = 2.0. J1 and J2 are associated with the exchange coupling through EO and EE azido bridges, respectively. The χT value of 1 (Fig. 3) smoothly increases as the temperature is lowered, attains a plateau at 70 K and quickly decreases in the lower temperature region. The susceptibility curve (inset of Fig. 3) increases monotonically when cooling, attains a shoulder in the temperature range 50–20 K and then increases achieving a maximum at 8.5 K. The shape of the shoulder is field dependent at T < 50 K but the temperature of the maximum remains unchanged. The theoretical analysis of the magnetic data of 16 matches well the experimental data in the temperature range 290–55 K. The best fit parameters are J1 (coupling through EO

Fig. 1 Crystal structure of [M(bipy)(N3)2] (M = Ni, Fe, Co, Zn) showing the atom numbering (ellipsoids are at the 30% probability level). The M–N bond lengths vary in the ranges 2.064(3)–2.145(4) Å for 1, 2.118(2)–2.189(2) Å for 2 and 2.132(2)–2.240(2) Å for 3. The values of the M(1)–N(3)–M(1a) bond angles are 101.5(1), 100.9(1) and 100.8(1)° 1 and 101.0(2)° 4 in 3. The EO and EE azido groups are planar. [The smallest N(3)–N(4)–N(5) and N(6)–N(7)–N(8) bond angles are 178.1(3) and 176.7(2)°, respectively]. Symmetry code for 1: a = x, 1 – y, –z; b 1 – x, 1 – y, –z; Symmetry code for 2: a = x, 1 – y, 1 – z; b 1 – x, 1 – y, 1 – z;
layered materials with alternating intralayer ferro- and antiferro-magnetic interactions. It is interesting to note that the spin vectors in the ferromagnetic chains are aligned parallel to the chain axis whereas in the case of the antiferromagnetic (or ferrimagnetic) chains they are arranged perpendicular to the chain axis in order to reconcile both the dipolar and exchange interactions. The question at hand concerning the chains exhibiting alternating ferro- and antiferro-magnetic interactions is to know the arrangement of the spin vectors for them. Our feeling is that the peculiar magnetic behaviour of 1–3 is related to the competition among the local anisotropy and the dipolar and exchange interactions.

§ The numerical expressions used for the analyses of the magnetic properties of 1–3 and 4 were obtained using the isotropic Hamiltonian ˆH = –JΣ [SₐSₐ–1 + αSₐSₐ–1] by fitting the theoretical susceptibility curves of the rings up to ten S = 1 (1) or six S = 5/2 (2) local spins instead of open chains. The theoretical development has been elaborated in ref. 6.
¶ Magnetic data for complex 2 are available from the authors.
