Received (in Cambridge, UK) 12th June 2001, Accepted 6th September 2001

A new manganese(III) oxamato dimer possessing an unprecedented MnIII(μ-O2CR)(μ-OH2⋯O2CR) core has been synthesised, structurally and magnetically characterised, and used as a catalyst for the oxidation of alkanes to alcohols and ketones by Bu3O2H and O2 in CH2Cl2 at rt.

The past two decades have seen a considerable interest in manganese redox enzymes, particularly those containing carboxylate-bridged dinuclear active sites.1 Among them, the less well understood but functionally important is manganese ribonucleotide reductase (MnRR), which catalyses the dioxygen-dependent reduction of ribonucleotides to deoxyribonucleotides in certain groups of bacteria.2 This key reaction for the ribonucleotide reductase (MnRR), which catalyses the dioxygen activation by the dimanganese center.2 That being so, studies concerning the reactivity of manganese model complexes bearing some structural features similar to those proposed for the different forms of the enzyme can help to understand the mechanism of conversion of ribonucleotides by MnRR.4 Here we report on the synthesis and general physical characterisation,† crystal and molecular structure,21 and magnetic properties of the manganese(II) dimer complex (Ph4P)2[Mn2(opba)2(H2O)3]·H2O·MeCN 1, where opba is o-phenylenebis(oxamato). We also report a preliminary investigation of the catalytic activity of I towards the oxidation of hydrocarbons with alkyl hydroperoxides in the presence of dioxygen under mild conditions.

The structure of I consists of non-centrosymmetric dinuclear manganese(II) complex anions, [Mn2(opba)]3−(H2O)3]2− (Fig. 1), tetraphenyolphosphonium cations and both water and acetonitrile solvent molecules. The coordination environment about each Jahn–Teller-elongated octahedral manganese atom is formed by two amide nitrogen and two carboxylate oxygen atoms of the tetaedranate opba ligand defining the equatorial plane and with the two labile axial positions being occupied by water and/or carboxylate oxygen atoms. In fact, within the dinuclear unit, a carboxylate group from one planar [Mn(opba)] moiety is axially bound to the manganese atom from the other moiety (syn–anti bidentate bridging mode),5 while a free carboxylate oxygen atom from the latter [Mn(opba)] fragment is hydrogen-bonded to an axial, manganese-bound water molecule of the former fragment [O(8)⋯O(14) separation of 2.702(9) Å]. This leads to an overall asymmetric doubly-bridged dimanganese(III) core which is reminiscent of the structure of the dioxorhodium(II) form of FeRR, but without the oxo bridge present therein.6 The Mn(1)⋯Mn(2) intramolecular separation through this unique nine-membered metallacyclic ring, MnIII2(μ-O2CR)(μ-OH2⋯O2CR), in I is 5.693(3) Å. This is ca. 2.5 Å longer than the corresponding distance in the related triply-bridged MnIII2(μ-OH⋯O2CR)2 species, which have been proposed as suitable structural models of the dimanganese(III) form of MnRR.6

The magnetic behaviour of I is typical of an antiferromagnetically-coupled dimanganese(III) pair. At room temperature, the product $\chi_M$ (with $M$ being the molar magnetic susceptibility per dinuclear unit and $T$ the temperature) is equal to 6.0 cm$^3$ mol$^{-1}$ K (6.9 $\mu_B$), a value which is consistent with two MnIII ($S = 2$) ions. Upon cooling, $\chi_M$ decreases from room temperature to 0.8 cm$^3$ mol$^{-1}$ K (2.5 $\mu_B$) at 2.0 K, whereas $\chi_M$ exhibits a characteristic maximum around 6.0 K, which unambiguously indicates a diamagnetic ground singlet ($S = 0$) pair spin state. The least-squares fitting of the magnetic susceptibility data gives $g = 2.00$ and $J = –2.0$ cm$^{-1}$ (where $H = –JS_1S_2$; $S_1 = S_2 = 2$). The value of the exchange coupling parameter for I compares well with that found for other weakly coupled di(μ-carboxylato)diamanganese(III) complexes ($J$ values of $–1.4$ and $–1.9$ cm$^{-1}$).7 On the other hand, this certainly weak, although non-negligible, antiferromagnetic coupling through the carboxylate bridge found in I emphasises the relative importance of the exchange pathways involving the bridging carboxylate groups for the analysis of the variations in the sign and the magnitude of the exchange coupling in (μ-oxo)(μ-carboxylato)diamanganese(III) complexes ($J$ values ranging from $+18.0$ to $–8.2$ cm$^{-1}$).6,6c

The oxidation catalytic activity of I has been examined in a non-coordinating solvent like methylene chloride and at room temperature using tert-butyl hydroperoxide as oxidant under aerobic conditions. The results for some representative alkanes

¹ Reactions were carried out at room temperature by adding a solution of the substrate (0.10 mmol) in CH2Cl2 (0.2 mL) to a stirred mixture of the metal catalyst (5.0 × 10⁻³ mmol) and BuO₂H (0.30 mmol) in CH2Cl2 (0.2 mL) under an O2 atmosphere for a period of 24 h. In the absence of catalyst no oxidation was observed. *Yields refer to GLC determination based on the starting substrate. With a reaction time of 72 h.

and alkyl arenes are summarised in Table 1. Complex I catalysed the oxidation of cyclohexane to the corresponding alcohol and ketone, cyclohexanol and cyclohexanone, respectively, with varying yields depending on the reaction time (entry 1). Interestingly, the cyclohexanol/cyclohexanone ratio dropped from 0.9 to 0.6 with longer reaction times, suggesting that secondary alcohols are further oxidised to ketones under the experimental conditions. It is also noteworthy that for our catalytic system the tertiary to secondary C–H bond relative reactivities (k₅/k₆; on a per bond basis) for the oxidation of adamantane was as high as 24 (entry 2). On the other hand, alkyl arenes such as toluene, ethylbenzene or diphenylmethane were oxidised selectively at the benzylic position to give the corresponding alcohol and ketone (entry 3). The oxidation of ethylbenzene and diphenylmethane afforded mixtures of the corresponding alcohol and ketone exclusively (entries 4 and 5, respectively). The total yields of benzylic oxygenation products followed the trend toluene < ethylbenzene < diphenylmethane (entries 3–5). Indeed, the oxidation efficiency along this series of alkyl arenes PhCH₂R (R = H, Me, Ph) correlates directly with the C–H bond strength, thus suggesting that C–H bond cleavage is the rate-determining step of the catalytic cycle. Further kinetic studies are in progress to determine the detailed mechanism and the exact chemical nature of the active oxidant in these biomimetic oxidations.

This work was supported by the Dirección General de Enseñanza Superior e Investigación Científica (Spain) through projects PB97-1411 and PB97-1397. R. R. thanks the Ministerio de Ciencia y Tecnología (Spain) for a grant. We are specially thankful to Pedro Pulanca for the assistance with the GLC measurements.

Notes and references

† Synthesis and selected data: to a solution of the diethyl ester derivative of the ligand (1.54 g, 5.0 mmol) in methanol (50 mL) was added a 25% methanol solution of Mn(NO₃)₂.H₂O (1.35 g, 5.0 mmol) then was added in small portions under stirring, and the resulting reaction mixture was further stirred for 15 min at room temperature. A brick-red microcrystalline solid formed abundantly which was collected by filtration and dried under vacuum. The filtered deep red solution was reduced to a final volume of 25 mL in a rotatory evaporator. Upon standing at 4 °C in a refrigerator, a second crop of crystals separated from the concentrated solution which was also collected and dried (60%). Anal. Calc. for C₁₅H₁₄Mn₂O₄.H₂O: C 40.67, H 10.17, N 4.84. Found: C 41.05, H 9.91, N 5.12%. (Me₂N)[Mn(oph)]₂H₂O (0.83 g, 2.0 mmol) was dissolved in water (50 mL) and the reaction mixture was filtered on paper to eliminate a small amount of solid particles. A solution of Ph₅P=Cl (0.75 g, 2.0 mmol) in acetonitrile (25 mL) was then added to the filtered deep brown aqueous solution. Well-shaped, brick-red elongated prisms of suitable for X-ray diffraction were deposited after a few hours of slow evaporation at room temperature. They were filtered off and air-dried (90%). vKBr/cm⁻¹: 3422s (O–H) from H₂O, 2254w (C≡N) from MeCN, 1669s and 1645vs (C=O), 1381s and 1280s (C=O) from opba. UV–Vis (MeCN) lg₁ₐₘₚₖ₎ₜₖ₁ₚ₄ = 10 (6 × 10⁻⁴ cm⁻¹ × 1.4 × 10⁻⁵), 225 (sh), 260 (6.0 × 10⁻⁴), 275 (sh), 340 (9.4 × 10⁻⁴) and 410 (sh).
