Summary: The humid plains of the lower Dauphiné area, located at the foothills of the northern French pre-Alps, between Grenoble and Lyon, are made of a complex of glacial and fluvial morphologies that have been occupied during a major part of the Holocene by marshes. In the framework of two programs funded by the Ministère de la Culture et de la Communication and the Agence Nationale de la Recherche, “PCR Peuplement et Milieu en Bas-Dauphiné (Isle Crémieu), de l’apparition de l’agriculture à l’époque moderne” (J.-F. Berger dir.) and “Paléohydrologie et humain-climat-environnement interactifs” (Pygmalion”, F. Arnaud dir.) and thanks to numerous archaeological operations previous to various building works, we had the opportunity to study the management of these peculiar landscapes by human societies since the Neolithic. A dozen of sites, mainly “natural” sequences and palaeohydrological structures (palaeochannel and drainage/irrigation ditches), but also “real” archaeological occupations, have provided wood charcoal and/or imbibed wood remains. It appears that vegetation changes recorded by charcoal and wood assemblages are mainly related to local changes (soils, local humidity) and triggered by human management of the swamps.

Key words: charcoal analysis, humid landscape management, hydrological systems, vegetation, Bas Dauphiné

INTRODUCTION

The humid plains of the lower Dauphiné areas are located at the foothills of the northern French pre-Alps, between Grenoble and Lyon. Colluvio-alluvial and/or lacustrine sedimentation progressively filled the glacial basin during the first part of the Holocene, before the development of peats during the Neolithic (Berger et al., 2008). In spite of its being occupied by marshes during the major part of the Holocene, the area has been intensively used by human societies since prehistoric times (Bernigaud et al., in press).

Thanks to numerous archaeological operations previous to various building works, we had the opportunity to study the management of these peculiar landscapes since the Neolithic. A dozen of sites (Fig. 1), mainly “natural” sequences and palaeohydrological structures (palaeochannel and drainage/irrigation ditches), but also “real” archaeological occupations, have provided wood charcoal and/or imbibed wood remains.

Charcoal from archaeological sites gives information on the wood gathered for fuel, which is usually collected in the surroundings (Chabal, 1997). Charcoal from hydraulic structures and fluvial archives witnesses either natural vegetation fire or anthropic activities, such as bank cleaning or agricultural fires (Delhon, 2005). Finally, imbibed wood remains have been found in peaty deposits, where they deposited and preserved in situ, or in the infilling of hydraulic structures and rivers palaeochannels.

RESULTS AND DISCUSSION

It appears (Fig. 2) that vegetation changes recorded by charcoal and wood assemblages are mainly related to local changes (soils, local humidity) and triggered by human management of the swamps. They also document human practices (cleaning of the river banks, agricultural practices), and climate impact seems to have only a secondary importance in local vegetation changes. Nevertheless, occurrences of mountain species (fir: *Abies alba*) or Mediterranean species...
(sclerophyllous oak: sclerophyllous *Quercus*) have been recorded and could have a climatic meaning.

**ACKNOWLEDGEMENTS**

This study is part of the programme "PCR Peuplement et Milieu en Bas-Dauphiné (Isle Crémieu), de l’apparition de l’agriculture à l’époque moderne », funded by the French Ministère de la Culture et de la Communication and of the programme « Pygmalion » funded by the ANR. Most of the 14C dates were done thanks to the « Artemis » program.
