Search for FCNC single top-quark production at $\sqrt{s} = 7$ TeV with the ATLAS detector

The ATLAS Collaboration

Abstract

A search for the production of single top-quarks via flavour-changing-neutral-currents is presented. Data collected with the ATLAS detector at a centre-of-mass energy of $\sqrt{s} = 7$ TeV, corresponding to an integrated luminosity of 2.05 fb$^{-1}$, are used. Candidate events with a semileptonic top-quark decay signature are classified as signal or background-like events by using several kinematic variables as input to a neural network. No signal is observed in the neural network output distribution and a Bayesian upper limit is placed on the production cross-section. The observed upper limit at 95% confidence level on the cross-section multiplied by the $t \rightarrow Wb$ branching fraction is measured to be $\sigma_{t\rightarrow Wb} \times B(t \rightarrow Wb) < 3.9$ pb. This upper limit is converted using a model-independent approach into upper limits on the coupling strengths $\kappa_{tug}/\Lambda < 6.9 \times 10^{-3}$ TeV$^{-1}$ and $\kappa_{tgc}/\Lambda < 1.6 \times 10^{-2}$ TeV$^{-1}$, where $\Lambda$ is the new physics scale, and on the branching fractions $B(t \rightarrow ug) < 5.7 \times 10^{-5}$ and $B(t \rightarrow cg) < 2.7 \times 10^{-4}$.

Keywords: top physics, heavy quark production, FCNC, single top quark

1. Introduction

The top quark is the heaviest elementary particle known, with a mass of $m_{t} = 173.2 \pm 0.9$ GeV [1] that is close to the electroweak symmetry breaking scale. For this reason it is an excellent object to test the Standard Model (SM) of particle physics. The properties of the top quark can be studied directly by searching for final states from t-quark decays or indirectly by searching for final states from top-quark pair-production via the strong interaction has been measured at the LHC [2, 3], and its cross-section is in good agreement with the prediction of the SM. Additionally, top quarks can be singly produced through three different processes: $t$-channel, $Wt$ associated production, and $s$-channel. Only $t$-channel single top-quark production has been observed so far [4, 5]. According to the SM of particle physics, flavour-changing-neutral-current (FCNC) processes are forbidden at tree level and suppressed at higher orders due to the Glashow-Iliopoulos-Maiani mechanism [7]. Extensions of the SM with new sources of flavour predict higher rates for FCNCs involving the top quark; these extensions include new exotic quarks [8], new scalars [9, 10], supersymmetry [11, 14], or technicolour [15] (for a review see Ref. [16]). If the new particles are heavy, which is consistent with the non-observation of low-mass new particles at the Tevatron and LHC, their effects on top-quark FCNCs can be parameterised in terms of a set of dimension-six gauge-invariant operators [17]. The predicted branching fractions for top quarks decaying to a quark and a photon, $Z$ boson, or gluon can be as large as $10^{-3}$ to $10^{-5}$ for certain regions of the parameter space in the models mentioned. For heavy new particles these branching fractions can be large, if the new particles couple strongly to the SM particles.

According to the corresponding values of the unitary Cabibbo-Kobayashi-Maskawa matrix, the top quark decays almost exclusively to a $W$ boson and a $b$ quark. FCNC top-quark decays can be studied directly by searching for final states with the corresponding decay particles [18, 19]. However, the $t \rightarrow qg$ mode, where $q$ denotes either an up quark $u$ or a charm quark $c$, is almost impossible to separate from generic multijet-production via quark chromodynamic (QCD) processes, and a much better sensitivity can be achieved in the search for anomalous single top-quark production. In the process studied here, a $u$ or $c$ quark and a gluon $g$ coming from the colliding protons interact to produce a single top-quark. The most general effective Lagrangian $\mathcal{L}_{\text{eff}}$ for this process resulting from dimension-six operators contains only tensor couplings [20] and it can be written as [21, 22]:

$$\mathcal{L}_{\text{eff}} = g_{s} \sum_{q=u,c} \frac{\kappa_{tug}^{\prime}}{\Lambda} (\sigma^{\mu\nu} T^{i} (f_{qL}^{i} P_{L} + f_{qR}^{i} P_{R}) q G_{\mu\nu}^{ij} + h.c.),$$

where the $\kappa_{tug}, \kappa_{tgc}$ are dimensionless parameters that relate the strength of the new coupling to the strong coupling constant $g_{s}$, $\Lambda$ is the new physics scale, related to the mass cutoff scale above which the effective theory breaks down. $T^{i}$ are the Gell-Mann matrices [23] and $\sigma^{\mu\nu} = \frac{1}{2}[\gamma^{\mu}, \gamma^{\nu}]$ transforms as a tensor under the Lorentz group. The $f_{qL,R}^{i}$ are chiral parameters normalised such that $|f_{qL}^{i}|^{2} + |f_{qR}^{i}|^{2} = 1$. The operator $P_{L} = \frac{1}{2}(1 - \gamma^{5})$ performs a left-handed projection, while $P_{R} = \frac{1}{2}(1 + \gamma^{5})$ performs a right-handed projection, where $\gamma^{5}$ represents the chirality operator. $G_{\mu\nu}^{ij}$ is the gauge-field tensor of the gluon and $t$ and $q$ are the fermion fields of the top and light quark, respectively.

The existence of FCNC operators allows not only the production of top quarks via $qg \rightarrow t$, but also the decays $t \rightarrow qg$. In the allowed region of parameter space for $\kappa_{tug}/\Lambda$ an experimentally favourable situation occurs when the FCNC production cross-section for single top-quarks is several picobarns, while the branching fraction for FCNC decays is very small, and top quarks can thus be reconstructed in the SM decay mode.
The W boson can decay into quark-antiquark pairs (W → q̅q) or a lepton-neutrino pair (W → ℓν). In this analysis only the decay into a lepton-neutrino pair, the leptonic decay, is considered. Thus the complete process searched for is q̅q → t → W(→ ℓν)b. Selected events are characterised by an isolated high-energy lepton (electron or muon), missing transverse momentum from the neutrino and exactly one jet, produced by the hadronisation of the b quark. Events with a W boson decaying into a τ lepton, where the τ decays into an electron or a muon are also selected. The process studied here can be differentiated from SM single top-quark production because the latter is usually accompanied by additional jets.

This analysis is the first search for FCNCs involving quarks and gluons at the LHC. A search for the 2 → 1 process gg → ℓ was performed by CDF [24], while D0 set limits on κqg/Λ and κyg/Λ by analysing the 2 → 2 processes gg → tā, ug → t̅g, and gg → t̅u and their c quark analogues [25].

2. Data sample and simulation

The ATLAS detector [26] is built from a set of cylindrical subdetectors, which cover almost the full solid angle around the interaction point.

ATLAS is composed of an inner tracking system close to the interaction point, surrounded by a superconducting solenoid providing a 2 T axial magnetic field, electromagnetic and hadronic calorimeters, and a muon spectrometer. The electromagnetic calorimeter is a high-granularity liquid-argon (LAr) sampling calorimeter with lead absorber. An iron-scintillator tile calorimeter provides hadronic energy measurements in the central pseudorapidity range. The endcap and forward regions are instrumented with LAr calorimeters for both electromagnetic and hadronic energy measurements. The muon spectrometer consists of three large superconducting toroids, a system of trigger chambers, and precision tracking chambers.

This analysis is performed using √s = 7 TeV pp-collision data recorded by ATLAS between March 22 and August 22, 2011. Only the periods in which all the subdetectors were operational are considered, resulting in a data sample with a total integrated luminosity of 2.05 ± 0.08 fb⁻¹ [27, 28].

Detector and trigger simulations are performed with the standard simulation of ATLAS within the GEANT4 [29, 30] framework. The same offline reconstruction methods used with data events are applied to the simulated samples. Minimum bias events generated by PYTHIA [31] are used to simulate multiple pp interactions, corresponding to the LHC operation with 50 ns bunch separation and an average of six additional pp interactions per bunch crossing.

For the simulation of FCNC production of single top-quarks, PROTONS [62] is used. The top quarks decay as expected in the SM, and only the leptonic decay of the W boson is considered. W bosons decaying into a τ lepton, where the τ decays into an electron or a muon are included in both the signal and all background samples. The CTEQ6L1 leading-order (LO) parton distribution functions (PDFs) are used and the hadronisation of signal events is simulated with PYTHIA using the AMB1 tunes [34] to the ATLAS collision data. It has been verified that the kinematics of the signal process are independent of the a priori unknown FCNC coupling.

Several SM processes are expected to have the same final-state topology as the signal. Samples of simulated events for the t-channel and Wt single top-quark processes are generated by the AcepMC program [35] with the CTEQ6L1 PDFs and hadronised with PYTHIA; for the s-channel process, the MC@NLO [36] generator with the CTEQ6.6 [37] PDFs interfaced to HERWIG [38] and JIMMY [39].

The ALPGEN [40] program with the CTEQ6L1 PDFs is interfaced to HERWIG and JIMMY to generate Wjets, Whb, Wc, Zc and Z+jets events with up to five additional partons. To remove overlaps between the n and n + 1 parton samples the MLM matching scheme [40] is used. The double counting between the inclusive W+n parton samples and samples with associated heavy-quark pair-production is removed utilising an overlap-removal method based on ΔR matching. The parameters of HERWIG, with the MRST LO** [41] PDFs, and JIMMY are tuned to ATLAS collision data with the corresponding AUET1 tunes [42]. Diboson backgrounds from WW, WZ and ZZ events are simulated using HERWIG. For the generation of SM tt events the MC@NLO generator with the CTEQ6.6 PDFs is used. The parton shower and the underlying event are added using HERWIG and JIMMY.

3. Event selection

Events are considered only if they were accepted by a single-lepton trigger [43]. The single-muon trigger threshold was pT = 18 GeV, and the single-electron trigger threshold was raised from an E_T of 20 GeV to 22 GeV for higher LHC luminosities.

Electron candidates are defined as clusters of cells in the electromagnetic calorimeter associated with a well-measured track fulfilling several quality requirements [44]. Electron candidates are required to satisfy p_T > 25 GeV and |η_{clus}| < 2.47, where η_{clus} is the pseudorapidity of the cluster of energy deposits in the calorimeter. A veto is placed on candidates in the calorimeter barrel-endcap transition region, 1.37 < |η_{clus}| < 1.52, where there is limited calorimeter instrumentation. High-p_T electrons associated with the W-boson decay can be mimicked by hadronic jets reconstructed as electrons, electrons from decays of heavy quarks, and photon conversions. Since signal electrons from the W-boson decay are typically isolated from hadronic jet activity, these backgrounds can be suppressed via isolation criteria which require minimal calorimeter activity and only low track p_T in an η-θ cone around the electron candidate. Calorimeter isolation requires the sum of the E_T in cells within a cone of ΔR = 0.3 around each electron with p_T > 25 GeV to satisfy Σ E_T(ΔR < 0.3)/p_T < 0.15. Similarly, the
Monte Carlo simulation scaled to the theoretical cross-section predictions. For the tagging algorithm exploits the properties of a three-dimensional calorimeter energy cluster as signal candidates are required to have a transverse momentum \( p_T \) and \( \sum E \) defined as

\[
E = \sum E_T(\Delta R < 0.3)/p_T < 0.15.
\]

Candidate events are required to have exactly one isolated lepton (\( \ell \)).

Jets are reconstructed using the anti-\( k_t \) algorithm with the distance parameter \( R \) set to 0.4. The jets are then corrected from the raw calorimeter response to the energies of the reconstructed particles using \( p_T \) and \( \eta \)-dependent factors, derived from simulated events and validated with data. Since the signal process gives rise to only one high-\( p_T \) jet, exactly one reconstructed jet with \( p_T > 25 \) GeV is required.

The magnitude of the missing transverse momentum \( E_T^{miss} \) is defined as \( E_T^{miss} = |E_T^{miss}| \), where \( E_T^{miss} \) is calculated using the calibrated three-dimensional calorimeter energy clusters associated with the jet together with either the calibrated calorimeter energy cluster associated with an electron or the \( p_T \) of a muon track. Transverse energy deposited in calorimeter cells but not associated with any high-\( p_T \) object is also included in the \( E_T^{miss} \) calculation. Due to the presence of a neutrino in the final state of the signal process, \( E_T^{miss} > 25 \) GeV is required. To further reduce the number of multijet background events, which are characterised by low \( E_T^{miss} \) and low values of reconstructed W-boson transverse mass \( m_T^{W} = \sqrt{2 |p_T^{lep} E_T^{miss} - |p_T^{lep}| \cdot E_T^{miss}|} \), the event selection requires \( m_T^{W} + E_T^{miss} > 60 \) GeV.

Finally, the selected jet has to be identified (b-tagged) as a b-quark jet. The tagging algorithm exploits the properties of a b-quark decay in a jet using neural-network techniques and the reconstruction of a secondary vertex, and has an identification efficiency measured to be about 57% in \( t\bar{t} \) events. Only 0.2% of light-quark jets and 10% of c-quark jets are mis-tagged as b-quark jets. The following samples are defined for this analysis: a “b-tagged sample” with exactly one b-tagged jet, and a “pretagged sample” without any b-tagging requirement.

Assuming a cross-section of 1 pb for FCNC single top-quark production, about 113 signal events in 2.05 fb\(^{-1} \) of collision data are expected in the b-tagged sample.

The normalisations for the various background processes are estimated either by using the experimental data or by using Monte Carlo simulation scaled to the theoretical cross-section predictions. For the W+Jets and Z+Jets backgrounds the kinematic distributions are modelled using simulated events, while the inclusive cross-sections are calculated to next-to-next-to-leading order (NNLO) with FEWZ. The dominant W+Jets background process is Wc production, whose \( k \)-factor is obtained by comparing the NLO and LO cross-sections calculated using MCFM. The W+(1 jet) and Z+(1 jet) background normalisation uncertainties are estimated from the uncertainty in the cross-section of the W/Z+(0 jet) process and the uncertainty in the cross-section ratio of W/Z+(1 jet) to W/Z+(0 jet). A cross-section uncertainty of 4% is assigned for the W/Z+(0 jet) process. Variations consistent with experimental data are made in ALPGEN to the factorisation and normalisation scale and to the matching parameters, and yield a 24% uncertainty on the cross-section ratio. Background contributions from the heavy-quark processes Wbb, Wcc and Wc have relative uncertainties of 50%, estimated using a tag-counting method in control regions. The \( t\bar{t} \) cross-section is normalised to the approximate NNLO-predicted value obtained using HATHOR. The SM single top-quark production cross-section is also calculated to approximate NNLO with HATHOR. A theoretical uncertainty of 10% is assigned for SM top-quark production. The normalisation of the cross-section for production of diboson events is obtained using NLO cross-section predictions and has an uncertainty of 5%.

Multijet events may be selected if a jet is misidentified as an isolated lepton or if the event has a non-prompt lepton that appears isolated. A binned maximum-likelihood fit to the \( E_T^{miss} \) distribution is used to estimate the multijet background normalisation. A template of the multijet background is modelled using electron-like jets selected from jet-triggered collision data and is referred to as a jet-electron model. Each jet has to fulfill the same \( p_T \) and \( \eta \) requirements as a signal lepton, contain at least four tracks to reduce the contribution from converted photons, and deposit 80–95% of its energy in the electromagnetic calorimeter. The uncertainty in the multijet background normalisation is estimated to be 50% by fitting the distribution of \( m_T^{W} \) instead of \( E_T^{miss} \), and using jet-electron models built from jet-triggered data samples with different average numbers of inelastic pp interactions per event. The shape of the jet-electron data sample is used to model the multijet background shape in the electron and muon channels. The validity of the model in both channels is verified by comparing distributions of multijet-sensitive variables to observed data.

In the b-tagged sample 26223 events are observed in data compared to a prediction of 24000 ± 7000 events from our estimates of SM backgrounds. Table summarises the event yield for each of the background processes considered. Each event yield uncertainty in Table combines the statistical uncertainty, originating from the limited size of the used samples, with the uncertainty in the cross-section or normalisation.
network infrastructure consists of one input node for each of the 11 input variables plus one bias node, 13 nodes in the hidden layer, and one output node which gives a continuous output in the interval $[-1, 1]$. The training is done with a mixture of 50% signal and 50% background events using about 650000 events, where the different background processes are weighted according to their expected numbers of events.

The $qg \rightarrow t \rightarrow b\ell\nu$ process is characterised by three main differences from SM processes that pass the event selection cuts. Firstly, in single top-quark production via FCNCs, the top quark is produced almost without transverse momentum. Therefore the $p_T$ distribution of the top quark is much softer than the $p_T$ distribution of top quarks produced through SM top-quark production, and the $W$ boson and $b$ quark from the top-quark decay are almost back-to-back with an opening angle near $\pi$. Secondly, unlike in the $W/Z+\text{jet}$ and diboson backgrounds, the $W$ boson from the top-quark decay has a very high momentum and its highly-boosted decay products have small opening angles. Lastly, the top-quark charge asymmetry differs between FCNC processes and SM processes. The FCNC processes are predicted to produce four times more single top quarks than anti-top quarks, whereas in SM single top-quark production and all other SM backgrounds this ratio is at most two. All possible discriminating variables such as momenta, relative angles, pseudorapidity, reconstructed particles masses, and lepton electric charge were explored, including variables obtained from the reconstructed $W$ boson and the top quark. To reconstruct the four-momentum of the $W$ boson, the neutrino four-momentum is derived from the measured $E_T^{miss}$, since it cannot be measured directly. The neutrino longitudinal momentum, $p_z^\nu$, is calculated by imposing a kinematic constraint on the $m_W$ invariant mass. The twofold ambiguity is resolved by choosing the smallest $|p_z^\nu|$ solution, since the $W$ boson is expected to be produced with small pseudorapidity. The top-quark candidate is reconstructed by adding the four-momentum of the $b$-tagged jet to the four-momentum of the reconstructed $W$ boson.

Eleven variables were selected as input to the neural network after testing for each variable the agreement between the back-
ground model and observed events in both the large sample of pretagged events and the b-tagged sample. The first ten variables are the charge and the $p_T$ of the lepton, the $p_T$, $\eta$ and mass of the $b$-tagged jet, the $\Delta R$ between the $b$-tagged jet and the charged lepton, the $\Delta R$ between the $b$-tagged jet and the reconstructed $W$ boson, the opening angle $\Delta \phi$ between the directions of the $b$-tagged jet and the reconstructed $W$ boson, the $p_T$ of the $W$ boson and the reconstructed top-quark mass. The last variable considered in the neural network is the $W$-boson helicity. This is calculated as $\cos \theta^*$, the cosine of the angle between the momentum of the charged lepton in the $W$-boson rest-frame and the momentum of the $W$ boson as seen in the top-quark rest-frame. Table 2 shows a summary of the used variables ordered by their importance. The importance of the variables is estimated using an iterative procedure, removing one variable at a time and recalculating the separation power. The ordering is done in terms of relevance defined as standard deviations of the additional separation power given by each variable. Distributions of the three most important variables in the pretagged sample and the $b$-tagged sample, normalised to the number of observed events, are shown in Figure 2. Since the neural network benefits from the correlation between variables and is trained to separate the signal process from all background processes, the naively expected variables are not the most important ones, but variables, which are highly correlated to them.

The resulting neural network output distributions for the various processes, scaled to the number of observed events in the pretagged sample are shown in Figure 2(a). Figure 2(b) shows these distributions in the $b$-tagged sample. Signal-like events have output values close to 1, whereas background-like events are accumulated near −1. We find good agreement between the neural network output distributions for data and simulated events in both the pretagged and $b$-tagged samples.

5. Systematic Uncertainties

Systematic uncertainties affect the signal acceptance, the normalisation of the individual backgrounds, and the shape of the neural network output distributions. All uncertainties described below lead to uncertainties in the rate estimation as well as distortions of the neural network output distribution and are implemented as such in the statistical analysis.

The momentum scale and resolution, as well as the trigger and identification efficiency for single leptons is measured in collision data using $Z \rightarrow \mu \mu$, $Z \rightarrow e \nu$, and $W \rightarrow e \nu$ decays and corrective scale factors are applied to the simulation. Uncertainties on these factors as functions of the lepton kinematics are around 5%. To evaluate the effect of momentum scale uncertainties, the event selection is repeated with the lepton momentum varied up and down by the uncertainty. For the momentum resolution uncertainties, the event selection is repeated with the lepton energy varied up and down by the uncertainty.

Table 2: Variables used as input to the neural network ordered by their importance.
peated with the lepton momentum smeared. The uncertainty in the jet energy scale, derived using information from test-beam data, collision data, and simulation varies between 2.5% and 8% (3.5% and 14%) in the central (forward) region, depending on jet $p_T$ and $\eta$ [48]. This includes uncertainties due to different compositions of jets initiated by gluons or light quarks in the samples and mis-measurements due to close-by jets. Additional uncertainties due to multiple $pp$ interactions are as large as 5% (7%) in the central (forward) region. Here, the central region is defined as $|\eta| < 0.8$. An additional jet energy scale uncertainty of up to 2.5%, depending on the $p_T$ of the jet, is applied for $b$-quark jets due to differences between jets initiated by gluons or light quarks as opposed to jets containing $b$-hadrons. To evaluate the effect of these uncertainties the energy of each jet is scaled up or down by the uncertainty and the change is also propagated to the missing transverse momentum calculation. An uncertainty of 2% is assigned for the jet reconstruction efficiency based on the agreement between efficiencies measured in minimum bias and QCD dijet events and simulated events [57]. For the $b$-tagging efficiencies and mis-tag rates, jet $p_T$- and $\eta$-dependent scale factors are applied to match simulated distributions with observed distributions and have uncertainties from 8–16% and 23–45%, respectively [48].

Systematic effects from mis-modelling in event generators are estimated by comparing different generators and varying parameters for the event generation. The effect of parton shower and hadronisation modelling uncertainties is evaluated by comparing two A\textsc{c\textsc{t}\textsc{q}}MC samples interfaced to HERWIG and PYTHIA, respectively. The amount of initial and final state radiation is varied by modifying parameters in PYTHIA. The parameters are varied in a range comparable to those used in the Perugia Soft/Hard tune variations [58]. These uncertainties, the parton shower modelling and variations of initial and final state radiation are evaluated for all processes involving top quarks including the signal. The impact of the choice of PDFs in the simulation is studied by re-weighting the events according to PDF uncertainty eigenvector sets (CTEQ6.6, MSTW2008 [59]) and estimated following the procedure described in [60]. The uncertainties for the two PDF sets are added in quadrature. To account for uncertainties connected with the simulation of the $W$+jets sample several parameters in the generation of these samples are varied and event kinematics are compared. The uncertainty in the measured integrated luminosity is estimated to be 3.7%.

The dominant uncertainties are the uncertainties in the jet energy scale, the initial and final state radiation variations, and uncertainties in the $b$-tagging efficiencies and mis-tag rates.

6. Results

A Bayesian statistical analysis [61, 62] using a binned likelihood method applied to the neural network output distributions for the electron and muon channel combined is performed to measure or set an upper limit on the FCNC single top-quark production cross-section.

Systematic uncertainties and their correlations among processes are included with a direct sampling approach where the same Gaussian shift is applied to each source, process, and bin for a given uncertainty. The posterior density function (pdf) is obtained by creating a large number of samples of systematic shifts. A separate likelihood distribution is obtained for each sample, and the final pdf is then the average over all of the individual likelihoods. This pdf gives the probability of the signal hypothesis as a function of the signal cross-section. Since no significant rate of FCNC single top-quark production is observed, an upper limit is set by integrating the pdf. To estimate the a priori sensitivity, we use a pseudo-dataset corresponding to the prediction from simulations (Asimov dataset) [63] and treated in the same way as the observed dataset. The resulting expected upper limit at 95% confidence level (C.L.) on the anomalous FCNC single top-quark production cross-section including all systematic uncertainties is 2.4 pb, while the corresponding observed upper limit is 3.9 pb, as shown in Figures 3(a) and 3(b), respectively. To visualise the observed upper limit in the neural network output distribution Figure 4 shows...
the FCNC single top-quark process scaled to observed upper limit on top of the SM background processes. As a cross-check we performed the full statistical analysis only for events with NN output > 0, which yields an observed upper limit at 95% C.L. of 5.9 pb. Using the NLO predictions for the FCNC single top-quark production cross-section [64, 65], the measured upper limit on the production cross-section is converted into limits on the coupling constants \( \kappa_{ug}/\Lambda \) and \( \kappa_{cg}/\Lambda \). Assuming \( \kappa_{cg}/\Lambda = 0 \) one finds \( \kappa_{ug}/\Lambda < 6.9 \times 10^{-3} \text{ TeV}^{-1} \) and assuming \( \kappa_{ug}/\Lambda = 0 \) one finds \( \kappa_{cg}/\Lambda < 1.6 \times 10^{-2} \text{ TeV}^{-1} \). Figure 5(a) shows the distribution of the upper limit for all possible combinations. Using the NLO calculation [64], upper limits on the branching fractions \( B(t \rightarrow ug) < 5.7 \times 10^{-5} \) assuming \( B(t \rightarrow cg) = 0 \), and \( B(t \rightarrow cg) < 2.7 \times 10^{-4} \) assuming \( B(t \rightarrow ug) = 0 \) are derived, as shown in Figure 5(b).

Figure 4: Distributions of the neural network output: Observed signal and simulated background output distribution normalised to the mean value of the simulated samples and the uncertainty in the background normalisation.

Figure 5: Upper limit (a) on the coupling constants \( \kappa_{ug}/\Lambda \) and \( \kappa_{cg}/\Lambda \) and (b) on the branching fractions \( t \rightarrow ug \) and \( t \rightarrow cg \).

7. Conclusion

In summary, a data sample selected to consist of events with an isolated electron or muon, missing transverse momentum and a \( b \)-quark jet has been used to search for FCNC production of single top-quarks at the LHC. No evidence for such processes is found and the upper limit at 95% C.L. on the production cross-section is 3.9 pb. The limits set on the coupling constants \( \kappa_{ug}/\Lambda \) and \( \kappa_{cg}/\Lambda \) and the branching fractions \( B(t \rightarrow ug) < 5.7 \times 10^{-5} \) assuming \( B(t \rightarrow cg) = 0 \), and \( B(t \rightarrow cg) < 2.7 \times 10^{-4} \) assuming \( B(t \rightarrow ug) = 0 \) are the most stringent to date on FCNC single top-quark production processes for \( qg \rightarrow t \) and improve on the previous best limits [25] by factors of 4 and 15, respectively.

8. Acknowledgements

We thank CERN for the very successful operation of the LHC, as well as the support staff from our institutions without whom ATLAS could not be operated efficiently.

13 Department for Physics and Technology, University of Bergen, Bergen, Norway
14 Physics Division, Lawrence Berkeley National Laboratory and University of California, Berkeley CA, United States of America
15 Department of Physics, Humboldt University, Berlin, Germany
16 Albert Einstein Center for Fundamental Physics and Laboratory for High Energy Physics, University of Bern, Bern, Switzerland
17 School of Physics and Astronomy, University of Birmingham, Birmingham, United Kingdom
18 *(a)Department of Physics, Bogazici University, Istanbul; (b)Division of Physics, Dogus University, Istanbul; (c)Department of Physics Engineering, Gaziantep University, Gaziantep; (d)Department of Physics, Istanbul Technical University, Istanbul, Turkey
19 *(a)INFN Sezione di Bologna; (b)Dipartimento di Fisica, Università di Bologna, Bologna, Italy
20 Physikalisches Institut, University of Bonn, Bonn, Germany
21 Department of Physics, Boston University, Boston MA, United States of America
22 Department of Physics, Brandeis University, Waltham MA, United States of America
23 *(a)Universidade Federal do Rio De Janeiro COPPE/EE/IF, Rio de Janeiro; (b)Federal University of Juiz de Fora (UFJF), Juiz de Fora; (c)Federal University of Sao Joao del Rei (UFSJ), Sao Joao del Rei; (d)Instituto de Fisica, Universidade de Sao Paulo, Sao Paulo, Brazil
24 Physics Department, Brookhaven National Laboratory, Upton NY, United States of America
25 *(a)National Institute of Physics and Nuclear Engineering, Bucharest; (b)University Politehnica Bucharest, Bucharest; (c)West University in Timisoara, Timisoara, Romania
26 Departamento de Fisica, Universidad de Buenos Aires, Buenos Aires, Argentina
27 Cavendish Laboratory, University of Cambridge, Cambridge, United Kingdom
28 Department of Physics, Carleton University, Ottawa ON, Canada
29 CERN, Geneva, Switzerland
30 Enrico Fermi Institute, University of Chicago, Chicago IL, United States of America
31 *(a)Departamento de Fisica, Pontificia Universidad Católica de Chile, Santiago; (b)Departamento de Física, Universidad Técnica Federico Santa María, Valparaíso, Chile
32 *(a)Institute of High Energy Physics, Chinese Academy of Sciences, Beijing; (b)Department of Modern Physics, University of Science and Technology of China, Anhui; (c)Department of Physics, Nanjing University, Jiangsu; (d)School of Physics, Shandong University, Shandong, China
33 Laboratoire de Physique Corpusculaire, Clermont Université and Université Blaise Pascal and CNRS/IN2P3, Aubiere Cedex, France
34 Nevis Laboratory, Columbia University, Irvington NY, United States of America
35 Niels Bohr Institute, University of Copenhagen, Kobenhavn, Denmark
36 *(a)INFN Gruppo Collegato di Cosenza; *(b)Dipartimento di Fisica, Università della Calabria, Arcavata di Rende, Italy
37 AGH University of Science and Technology, Faculty of Physics and Applied Computer Science, Krakow, Poland
38 The Henryk Niewodniczanski Institute of Nuclear Physics, Polish Academy of Sciences, Krakow, Poland
39 Physics Department, Southern Methodist University, Dallas TX, United States of America
40 Physics Department, University of Texas at Dallas, Richardson TX, United States of America
41 DESY, Hamburg and Zeuthen, Germany
42 Institut für Experimentelle Physik IV, Technische Universität Dortmund, Dortmund, Germany
43 Institut für Kern- und Teilchenphysik, Technical University Dresden, Dresden, Germany
44 Department of Physics, Duke University, Durham NC, United States of America
45 SUPA - School of Physics and Astronomy, University of Edinburgh, Edinburgh, United Kingdom
46 Fachhochschule Wiener Neustadt, Johannes Gutenbergstrasse 3 2700 Wiener Neustadt, Austria
47 INFN Laboratori Nazionali di Frascati, Frascati, Italy
48 Fakultät für Mathematik und Physik, Albert-Ludwigs-Universität, Freiburg i.Br., Germany
49 Section de Physique, Université de Genève, Geneva, Switzerland
50 *(a)INFN Sezione di Genova; *(b)Dipartimento di Fisica, Università di Genova, Genova, Italy
51 *(a)E.Andronikashvili Institute of Physics, Tbilisi State University, Tbilisi; *(b)High Energy Physics Institute, Tbilisi State University, Tbilisi, Georgia
52 II Physikalisches Institut, Justus-Liebig-Universität Giessen, Giessen, Germany
53 SUPA - School of Physics and Astronomy, University of Glasgow, Glasgow, United Kingdom
54 II Physikalisches Institut, Georg-August-Universität, Göttingen, Germany
55 Laboratoire de Physique Subatomique et de Cosmologie, Université Joseph Fourier and CNRS/IN2P3 and Institut National Polytechnique de Grenoble, Grenoble, France
56 Department of Physics, Hampton University, Hampton VA, United States of America
57 Laboratory for Particle Physics and Cosmology, Harvard University, Cambridge MA, United States of America
58 *(a)Kirchhoff-Institut für Physik, Ruprecht-Karls-Universität Heidelberg, Heidelberg; *(b)Physikalisches Institut, Ruprecht-Karls-Universität Heidelberg, Heidelberg; *(c)ZITI Institut für technische Informatik, Ruprecht-Karls-Universität
Heidelberg, Mannheim, Germany
Faculty of Applied Information Science, Hiroshima Institute of Technology, Hiroshima, Japan
Department of Physics, Indiana University, Bloomington IN, United States of America
Institut für Astro- und Teilchenphysik, Leopold-Franzens-Universität, Innsbruck, Austria
University of Iowa, Iowa City IA, United States of America
Department of Physics and Astronomy, Iowa State University, Ames IA, United States of America
Joint Institute for Nuclear Research, JINR Dubna, Dubna, Russia
KEK, High Energy Accelerator Research Organization, Tsukuba, Japan
Graduate School of Science, Kobe University, Kobe, Japan
Faculty of Science, Kyoto University, Kyoto, Japan
Kyoto University of Education, Kyoto, Japan
Instituto de Física La Plata, Universidad Nacional de La Plata and CONICET, La Plata, Argentina
Physics Department, Lancaster University, Lancaster, United Kingdom
INFN Sezione di Lecce; (b) Dipartimento di Fisica, Università del Salento, Lecce, Italy
Olive Lodge Laboratory, University of Liverpool, Liverpool, United Kingdom
Department of Physics, Jožef Stefan Institute and University of Ljubljana, Ljubljana, Slovenia
School of Physics and Astronomy, Queen Mary University of London, London, United Kingdom
Department of Physics and Astronomy, University College London, London, United Kingdom
Laboratoire de Physique Nucléaire et de Hautes Energies, UPMC and Université Paris-Diderot and CNRS/IN2P3, Paris, France
Fysiska institutionen, Lunds universitet, Lund, Sweden
Departamento de Física Teorica C-15, Universidad Autonoma de Madrid, Madrid, Spain
Institut für Physik, Universität Mainz, Mainz, Germany
School of Physics and Astronomy, University of Manchester, Manchester, United Kingdom
CPPM, Aix-Marseille Université and CNRS/IN2P3, Marseille, France
Department of Physics, University of Massachusetts, Amherst MA, United States of America
Department of Physics, McGill University, Montreal QC, Canada
School of Physics, University of Melbourne, Victoria, Australia
Department of Physics, The University of Michigan, Ann Arbor MI, United States of America
Department of Physics and Astronomy, Michigan State University, East Lansing MI, United States of America
INFN Sezione di Milano; (b) Dipartimento di Fisica, Università di Milano, Milano, Italy
B.I. Stepanov Institute of Physics, National Academy of Sciences of Belarus, Minsk, Republic of Belarus
National Scientific and Educational Centre for Particle and High Energy Physics, Minsk, Republic of Belarus
Department of Physics, Massachusetts Institute of Technology, Cambridge MA, United States of America
Group of Particle Physics, University of Montreal, Montreal QC, Canada
P.N. Lebedev Institute of Physics, Academy of Sciences, Moscow, Russia
Institute for Theoretical and Experimental Physics (ITEP), Moscow, Russia
Moscow Engineering and Physics Institute (MEPhI), Moscow, Russia
Skobeltsyn Institute of Nuclear Physics, Lomonosov Moscow State University, Moscow, Russia
Fakultät für Physik, Ludwig-Maximilians-Universität München, München, Germany
Max-Planck-Institut für Physik (Werner-Heisenberg-Institut), München, Germany
Nagasaki Institute of Applied Science, Nagasaki, Japan
Graduate School of Science, Nagoya University, Nagoya, Japan
INFN Sezione di Napoli; (b) Dipartimento di Scienze Fisiche, Università di Napoli, Napoli, Italy
Department of Physics and Astronomy, University of New Mexico, Albuquerque NM, United States of America
Institute for Mathematics, Astrophysics and Particle Physics, Radboud University Nijmegen/Nikhef, Nijmegen, Netherlands
Nikhef National Institute for Subatomic Physics and University of Amsterdam, Amsterdam, Netherlands
Department of Physics, Northern Illinois University, DeKalb IL, United States of America
Budker Institute of Nuclear Physics, SB RAS, Novosibirsk, Russia
Department of Physics, New York University, New York NY, United States of America
Ohio State University, Columbus OH, United States of America
Faculty of Science, Okayama University, Okayama, Japan
Homer L. Dodge Department of Physics and Astronomy, University of Oklahoma, Norman OK, United States of America
Department of Physics, Oklahoma State University, Stillwater OK, United States of America
Palacky University, RCP TM, Olomouc, Czech Republic
Center for High Energy Physics, University of Oregon, Eugene OR, United States of America
LAL, Univ. Paris-Sud and CNRS/IN2P3, Orsay, France
Department of Physics, University of Illinois, Urbana IL, United States of America
Department of Physics and Astronomy, University of Uppsala, Uppsala, Sweden
Instituto de Física Corpuscular (IFIC) and Departamento de Física Atómica, Molecular y Nuclear and Departamento de Ingeniería Electrónica and Instituto de Microelectrónica de Barcelona (IMB-CNM), University of Valencia and CSIC, Valencia, Spain
Department of Physics, University of British Columbia, Vancouver BC, Canada
Department of Physics and Astronomy, University of Victoria, Victoria BC, Canada
Waseda University, Tokyo, Japan
Department of Particle Physics, The Weizmann Institute of Science, Rehovot, Israel
Department of Physics, University of Wisconsin, Madison WI, United States of America
Fakultät für Physik und Astronomie, Julius-Maximilians-Universität, Würzburg, Germany
Fachbereich C Physik, Bergische Universität Wuppertal, Wuppertal, Germany
Department of Physics, Yale University, New Haven CT, United States of America
Yerevan Physics Institute, Yerevan, Armenia
Domaine scientifique de la Doua, Centre de Calcul CNRS/IN2P3, Villeurbanne Cedex, France
Faculty of Science, Hiroshima University, Hiroshima, Japan
a Also at Laboratori de Instrumentacio e Física Experimental de Particulas - LIP, Lisboa, Portugal
b Also at Facultade de Ciencias and CFNUL, Universidade de Lisboa, Lisboa, Portugal
c Also at Particle Physics Department, Rutherford Appleton Laboratory, Didcot, United Kingdom
d Also at TRIUMF, Vancouver BC, Canada
e Also at Department of Physics, California State University, Fresno CA, United States of America
f Also at Novosibirsk State University, Novosibirsk, Russia
g Also at Fermilab, Batavia IL, United States of America
h Also at Department of Physics, University of Coimbra, Coimbra, Portugal
i Also at Università di Napoli Parthenope, Napoli, Italy
j Also at Institute of Particle Physics (IPP), Canada
k Also at Department of Physics, Middle East Technical University, Ankara, Turkey
l Also at Louisiana Tech University, Ruston LA, United States of America
m Also at Department of Physics and Astronomy, University College London, London, United Kingdom
n Also at Group of Particle Physics, University of Montreal, Montreal QC, Canada
o Also at Department of Physics, University of Cape Town, Cape Town, South Africa
p Also at Institute of Physics, Azerbaijan Academy of Sciences, Baku, Azerbaijan
q Also at Institut für Experimentalphysik, Universität Hamburg, Hamburg, Germany
r Also at Manhattan College, New York NY, United States of America
s Also at School of Physics, Shandong University, Shandong, China
t Also at CPPM, Aix-Marseille Université and CNRS/IN2P3, Marseille, France
u Also at School of Physics and Engineering, Sun Yat-sen University, Guangzhou, China
v Also at Academia Sinica Grid Computing, Institute of Physics, Academia Sinica, Taipei, Taiwan
w Also at DSM/IRFU (Institut de Recherches sur les Lois Fondamentales de l’Univers), CEA Saclay (Commissariat a l’Energie Atomique), Gif-sur-Yvette, France
x Also at Section de Physique, Université de Genève, Geneva, Switzerland
y Also at Departamento de Física, Universidad de Minho, Braga, Portugal
z Also at Department of Physics and Astronomy, University of South Carolina, Columbia SC, United States of America
aa Also at Institute for Particle and Nuclear Physics, Wigner Research Centre for Physics, Budapest, Hungary
ab Also at California Institute of Technology, Pasadena CA, United States of America
ac Also at Institute of Physics, Jagiellonian University, Krakow, Poland
ad Also at LAL, Univ. Paris-Sud and CNRS/IN2P3, Orsay, France
ae Also at Department of Physics and Astronomy, University of Sheffield, Sheffield, United Kingdom
af Also at Department of Physics, Oxford University, Oxford, United Kingdom
ag Also at Institute of Physics, Academia Sinica, Taipei, Taiwan
ah Also at Department of Physics, The University of Michigan, Ann Arbor MI, United States of America
ai Also at Laboratoire de Physique Nucléaire et de Hautes Energies, UPMC and Université Paris-Diderot and CNRS/IN2P3, Paris, France
