Abstract

The decays \( K^0 \to \pi^0 \gamma \gamma \) are calculated within the framework of chiral perturbation theory. The amplitude for \( K^0 \to \pi^0 \gamma \gamma \) is found to be finite at the one-loop level yielding a branching ratio of \( 6.8 \times 10^{-7} \). The decay spectra of both decays are very characteristic and provide good tests of the effective chiral symmetry realization of the Standard Model.

In a recent paper [1] we have extended the methods of chiral perturbation theory to non-leptonic electroweak processes and applied them to $K \to \pi \pi$ decays. The purpose of this letter is to present the results of a new application within this framework to $K_L, S \to \pi^0 \gamma \gamma$ decays. As

present, there is only an experimental upper limit for the $K_L \to \pi^0 \gamma \gamma$ branching ratio [2]

$$\frac{\Gamma(K_L \to \pi^0 \gamma \gamma)}{\Gamma(K_L \to \text{all})} < 2.4 \times 10^{-4}, \quad (1)$$

but improved experiments on rare $K$-decays, which are under way, may well be able to measure this decay mode in the near future. Chiral perturbation theory is ideally suited to describe such decays because the only hadrons involved are pseudoscalar mesons and, furthermore, the characteristic momenta are small compared to the natural scale of chiral symmetry breaking. As we will show, the predictions for $K_L, S \to \pi^0 \gamma \gamma$ decays are free from arbitrary parameters and provide good tests of the effective chiral symmetry realization of the Standard Model.

The decay $K_L \to \pi^0 \gamma \gamma$ shares with $K_L \to \pi^0 \nu \bar{\nu}$ [4] the remarkable property of being finite at the one-loop level in chiral perturbation theory. This can be understood by investigating the possible local counterterms of dimension four in the effective chiral Lagrangian which can induce these transitions. The counterterms have to be constructed with $U(x)$, the $3 \times 3$ unitary matrix which incorporates non-linearly the octet of pseudoscalar fields, covariant derivatives $D^\mu U(x)$ and external gauge fields $F^\mu_\nu(x), F^\mu_\nu(x)$ [1]. Neglecting the part of the non-leptonic $AS = 1$ weak Hamiltonian transforming like a $27_L \times 1_R$ operator, and up to arbitrary coupling constants, there are three possible counterterms with the required transformation properties under chiral $SU(3)_L \times SU(3)_R$:

$$C_1 \equiv \text{tr}(\lambda_{\mu \nu} F_{\mu \nu} U^\dagger F_{\mu \nu} U^\dagger), \quad (2a)$$

$$C_2 \equiv \text{tr}(\lambda_{\mu \nu} U F_{\mu \nu} U^\dagger F_{\mu \nu} U^\dagger), \quad (2b)$$

$$C_3 \equiv \text{tr}(\lambda_{\mu \nu} F_{\mu \nu} U F_{\mu \nu} U^\dagger). \quad (2c)$$

Notice that there are no explicit mass terms of the required dimension, counterterms with $D \cdot \bar{U}$ cannot contribute because $D(p) = 0$ for neutral fields, and the corresponding expressions with $F_{\mu \nu} U$ replaced by $\lambda_{\mu \nu} F_{\mu \nu} U$ are forbidden by CPS-symmetry [5]. For external photons we have

$$\lambda_{\mu \nu} F_{\mu \nu} U = 0 \quad (3a)$$

$$\lambda_{\mu \nu} F_{\mu \nu} = 0 \quad (3b)$$

and therefore

$$C_1 = C_2 = C_3. \quad (4)$$

Expanding $C_1$ in powers of meson fields $\pi$, one finds

$$C_1 = \lambda_{\mu \nu} F_{\mu \nu}(\pi^+ \pi^- + O(\lambda^3)) \quad (5)$$

with no linear or quadratic $K^0, \pi^0 \pi^0$ terms in the brackets.

In principle, there could also be counterterms of strong + electromagnetic origin which become relevant when combined with the $AS = 1$ effective Lagrangian. With two external gauge fields present, the only counterterm available with dimension four is [3]

$$\lambda_{\mu \nu} \text{tr}(U F_{\mu \nu} U^\dagger F_{\mu \nu} U^\dagger). \quad (6)$$

Similar to (5), there are again no neutral meson fields in the linear or quadratic terms of (6). From this analysis we then conclude that there are indeed counterterms of dimension four for $K^+ + \pi^+ \pi^0$, but neither for $K^0 \to \pi^0 \pi^0$ nor for $K_L \to \pi^0 \gamma \gamma$. Therefore, both $K_S \to \gamma \gamma$ and $K_L \to \pi^0 \gamma \gamma$ must be

---

* See, e.g., Refs. [3] where earlier references can also be found.
finite at the one-loop level. The finiteness of $\kappa_3 + \gamma_3$ was confirmed by two recent calculations [4]. We want to emphasize, however, that the counterterms discussed in Ref. [4a] are not relevant counterterms for the one-loop amplitude contrary to the authors' claim.

The Lagrangian for non-leptonic $\Delta S = 1$ electroweak transitions has been given in Ref. [1]. From the calculational point of view, we have found it a considerable simplification to diagonalize simultaneously the covariant kinetic and mass terms of order $G_F$ (Fermi coupling constant) which are quadratic in the pseudoscalar fields. In this diagonal basis, there is neither a $K + \pi$ coupling nor a $K + \pi\pi$ vertex. The effective couplings relevant to the $K^0 + n^0\gamma\gamma$ transition are then given by the Lagrangian

$$L_{\text{eff}} = \frac{G_F}{\sqrt{2}} \left( L_1 + L_2 + L_3 \right) + \text{h.c.}$$

(7a)

$$G_F = \frac{G_F}{\sqrt{2}} \left| e \right|^4 \left| \theta \right|^2 , \quad \left| \theta \right|^2 = 5.1$$

(7b)

$$L_1 = 3K^0\bar{\nu}_\mu K D^\mu \gamma^\nu + 2K^0\bar{\nu}_\mu K_D^\mu D^\nu - 2\nu_D^\mu D^\mu K D^\nu +$$

$$+ \nu D^\mu K^0\bar{\nu}_\mu K D^\nu + \bar{\nu}_\mu K^0\bar{\nu} D^\mu D^\nu + \nu D^\mu K^0\bar{\nu}_\mu K D^\nu +$$

$$+ \nu \bar{\nu}_\mu K^0 \bar{\nu} D^\mu D^\nu + \bar{\nu}_{\bar{\nu} \mu} K^0 \bar{\nu} D^\mu D^\nu$$

(7c)

$$L_2 = K^0\bar{\nu}_\mu K D^\mu \gamma^\nu + K^0\bar{\nu}_\mu K D^\mu \gamma^\nu + 2K^0\bar{\nu}_\mu K D^\mu \gamma^\nu + 2\nu_D^\mu D^\mu K D^\nu +$$

$$+ \nu D^\mu K^0\bar{\nu}_\mu K D^\nu + \bar{\nu}_\mu K^0\bar{\nu} D^\mu D^\nu + \nu D^\mu K^0\bar{\nu}_\mu K D^\nu +$$

$$+ \nu \bar{\nu}_\mu K^0 \bar{\nu} D^\mu D^\nu + \bar{\nu}_{\bar{\nu} \mu} K^0 \bar{\nu} D^\mu D^\nu$$

(7d)

$$L_3 = 2K^0\bar{\nu}_\mu K D^\mu \gamma^\nu + m^2 \bar{\nu}_\mu \bar{\nu} D^\mu D^\nu$$

(7e)

$$D^\mu \gamma_\mu = 3 \mu^\mu + i e \phi^\mu , \quad D^\mu \gamma_\mu = 3 \phi^\mu (\phi = K, \pi)$$

(7f)

Here, $L_1$ contains the quartic terms of the usual $\Delta S = 1$ weak Lagrangian in the exponential parametrization of $U(x)$, while $L_2$ and $L_3$ arise from

the strong interaction Lagrangian (including the chiral symmetry breaking mass term) through the diagonalization procedure described above.

The Feynman diagrams for $K^0 + n^0\gamma\gamma$ transitions at the one-loop level are shown in Fig. 1, where a small box denotes vertices generated by $L_{\text{eff}}$ in Eq. (7). Note that in the diagonal basis the relation between the one-loop amplitudes for $K_L + n^0\gamma\gamma$ and $K_S + \gamma\gamma$ is manifest. The diagrams of Fig. 1 are exactly the diagrams needed for the calculation of $K_L + \gamma\gamma$ [4] except that there is an additional $s^0$ at the weak vertices. It is therefore no surprise that we do finally obtain the same loop functions for both amplitudes with slightly different vertex factors only.

We have established the relation between the $K^0 + n^0\gamma\gamma$ and $K^0 + \gamma\gamma$ loop amplitudes diagram by diagram confirming the results of Refs. [4].

The final result for the $K_L + n^0\gamma\gamma$ amplitude at the one-loop level is

$$A(K_L(p) \rightarrow n^0(p') + \gamma(q_1) + \gamma(q_2)) = \frac{G_F}{2\pi} \sqrt{2} \left| q_1 \right| \left| q_2 \right| (2q_2\mu_1 - q_2\mu_2) \times$$

$$\times \left[ (1 - m^2_q/q^2)\epsilon_0(q^2/m^2_q) - (1 - m^2_q/q^2 - m^2_s/q^2)\epsilon_0(q^2/m^2_s) \right]$$

(8)

with $q = q_1 + q_2$ and

$$F(z) = \begin{cases} 1 - 4[\arccos \sqrt{2}/2]/z & z \leq 4 \\ 1 - z/z + (\ln 1 - \sqrt{1 - z/z})^2/z + 212/23 & z \geq 4 \end{cases}$$

(9a)

$$F(z) \approx -z/12 .$$

(9b)

Notice that the $\pi^0\pi^0$ and $K^0K^0$ intermediate states give separately finite and gauge invariant contributions. Of the four possible invariant amplitudes which govern a general weak decay [6] $M_1 + M_2\gamma\gamma$ with two (pseudo) scalar particles $M_1, M_2$ of the same charge, a single one appears at the one-loop level. Two of those invariant amplitudes are eliminated by our assumption of CP invariance which we shall drop later. The absence of the

*) We assume CP conservation at this point.
second CP conserving amplitude is related to a rather general phenomenon
of non-leptonic photon weak decays. It is due to the mismatch between
the minimum number of powers of momenta required by gauge invariance and
those that chiral perturbation theory can provide at the one-loop level.
The same phenomenon explains the absence of $K^+ \to \pi^+\pi^0\pi^0$ [1] and of $K^+ \to
\pi^+\pi^0\gamma\gamma$ [6] transitions to lowest order in chiral perturbation theory.

From (8) we obtain the total decay rate

$$\Gamma(K_L \to \pi^0\gamma\gamma) = \frac{(q^2/M_{K^0})^2}{(4\pi)^5} \int_0^\infty \frac{dz}{z} \left[ \left(1 - \frac{z}{r_n}\right)^2 \right] \left(1 + \frac{r_n^2}{z} - \frac{z}{r_n^2}\right) \left[\frac{(1 + r_n^2 - z)}{r_n^2}\right]^2 \left(\frac{1}{z - r_n^2}\right)^2 \left[\frac{(1 + r_n^2 - z)}{r_n^2}\right]^2 \left(\frac{1}{z - r_n^2}\right)^2,$$

(10)

where $\lambda(a, b, c) = a^2 + b^2 + c^2 - 2(ab + bc + ca)$. The predicted $q^2$-spectrum
of this decay mode is very characteristic and is shown in Fig. 2 (full curve).

For the sake of comparison, we have also plotted in the same figure the
spectrum expected from phase space alone (dashed curve). The peaking of
the predicted distribution at large $z$ is due to the rapidly rising
absorptive part of the $n\pi$ intermediate state. Altogether, the absorptive
part contributes 62% to the total rate. Using $|g_{\gamma \gamma}| = 5.1$ as determined
from $K \to n\pi$ decays, we get from (10) for the $K_L \to \pi^0\gamma\gamma$ branching ratio

$$\frac{\Gamma(K_L \to \pi^0\gamma\gamma)}{\Gamma(K_L \to \pi^0\pi^0)} = 6.8 \times 10^{-7},$$

(11)

which is significantly below the present experimental upper bound (1).

For high-statistics $K$-decay experiments are, however, expected to
reach the required sensitivity to measure this branching ratio.

We now turn to a discussion of the decay $K_S \to \pi^0\gamma\gamma$ which proceeds
via the diagram shown in Fig. 3. The $\pi^0(\pi^0\gamma\gamma$ vertices are induced by the
Adler [7a], Bell and Jackiw [7b] anomaly and are incorporated in chiral
perturbation theory in the so-called Wess-Zumino-Witten (WZW) term

When restricted to external $\pi^0(\pi^0\gamma\gamma$ fields, the WZW term has the simple
form

$$L_{\text{WZW}} = \frac{1}{8\pi F_0} \epsilon_{\mu\nu\rho\sigma} p^\mu p^\nu (\pi^0 \gamma^\rho \pi^0 \gamma^\sigma),$$

(12)

The weak vertices are the usual ones in terms of the octet coupling
constant $G_B$. Both the $\pi^0$-contribution and the difference between $f_L$ and
$f_T$ are higher order in chiral perturbation theory and are not included
in (12). This is evident for $f_L \to f_T$ and follows for the $\pi^0$-contribution
from the absence of a local counterterm for $K^0 \to \pi^0\gamma\gamma$ of dimension four.
In any case, the $\pi^0$-contribution turns out to be very small and the $K_S \to
\pi^0\gamma\gamma$ amplitude can be expected to be quite insensitive to higher order
chiral corrections.

We want to emphasize that the situation for chiral perturbation
theory is much more favourable for $K_S \to \pi^0\gamma\gamma$ than for $K_L \to \gamma\gamma$ because of
two reasons. The first observation is that $K_L \to \gamma\gamma$ vanishes in lowest
order because the $\pi^0$ and the $\pi^0$ pole contributions exactly cancel. A leading
log calculation [9] of the higher order corrections has found the
$K_L \to \gamma\gamma$ amplitude to be very sensitive to SU(3) breaking. A more detailed
calculation involving also finite counterterms is necessary before any
realistic prediction for the $K_L \to \gamma\gamma$ decay rate can be given. In contrast
to $K_L \to \pi\pi$, the transition $K_S \to \pi^0\gamma\gamma$ is non-vanishing in lowest order
chiral perturbation theory. Moreover, the invariant mass of the photon
pair is obviously smaller for $K_S \to \pi^0\gamma\gamma$ because

$$q^2 \leq (M_{K^0} - m_{\pi^0})^2 = 0.53 M_{K^0}^2.$$

(13)

The diagram of Fig. 3 leads to the amplitude

$$A(K_S(p) \to \pi^0(p') + \pi^0(q_1) + \pi^0(q_2)) = \frac{G_B}{\pi} \epsilon_{\alpha\beta\gamma\delta} \epsilon^{\beta\gamma\nu\rho}(q_1) \epsilon^{\nu\rho}\epsilon_{\mu\nu\pi^0}(q_2)^0.$$
\[ r_{n} = \frac{H_{n}}{H_{K_{0}}} \quad \quad z = q^{2}/M_{K_{0}}^{2} \]

keeping \( f_{n} \neq f_{0} \) to display the sensitivity to chiral corrections. We observe that the amplitude (14) vanishes in the SU(3) limit and that there is again only one of two possible invariant amplitudes consistent with CP conservation. The absence of the second invariant amplitude is again due to the mismatch in powers of momenta required by gauge and chiral invariance, whereas the SU(3) limit can be understood most easily by employing a U-spin analysis. From Eq. (14) we obtain the decay rate

\[
\Gamma(K_{S} \rightarrow \pi^{0} \gamma) = \frac{|G_{0}|^{2} M_{K_{0}}^{2}}{(4 \pi)^{3}} \int_{0}^{z} \frac{dz}{z^{2}} \left( 2 \sqrt{z} \right) \frac{2}{2} \left( \frac{2}{3} \right) \left( \frac{z-r_{n}^{2}}{z-r_{n}^{2}} \right) \frac{r_{n}}{z-r_{n}^{2}} \frac{r_{n}^{2}}{z-r_{n}^{2}} \frac{r_{n}^{2}}{z-r_{n}^{2}}
\]

(15)

where the irrelevant imaginary part of the \( n \)-pole has been omitted. Of course, the total rate is completely dominated by the pion pole. Therefore, we restrict ourselves to the region

\[
0.2 \leq z \leq (1-r_{n}^{2})^{2}
\]

(16)

where the spectrum can be used to test the chiral structure of weak vertices. In Fig. 4 we show the normalized \( q^{2} \)-distribution for \( K_{S} \rightarrow \pi^{0} \gamma \) (full curve) with the cut \( z \geq 0.2 \). The pion pole contribution shown is also shown in the same figure (dotted curve). For the sake of comparison, the dashed curve shows the spectrum obtained with momentum independent weak vertices, i.e., with the expression in brackets in Eq. (14) replaced by

\[
\frac{1}{z-r_{n}^{2}}
\]

(17)

It is clear that even for large \( z \) the rate is very much dominated by the pion contribution. The smallness of the \( n \)-contribution is mainly due to the chiral vertex structure \( (2-3z+r_{n}^{2})/3 \). The curves in Fig. 4 are drawn using the one-loop corrected value \( f_{n}/f_{0} \). But, as far as we neglect the difference to the symmetric value \( f_{n} = f_{0} \), the smallness of the \( n \)-contribution could not be seen in the figure. With sufficient statistics, the chiral structure of weak vertices could be experimentally tested. The relevant branching ratio is

\[
\frac{\Gamma(K_{S} \rightarrow \pi^{0} \gamma)}{\Gamma(K_{S} \rightarrow \phi \gamma)} = 3.8 \times 10^{-7} \quad (18)
\]

We shall finally discuss the question of CP violation in these decays. It is clear that the \( K_{S}^{0} \) component in the \( K_{S} \) state can now induce a CP violating amplitude at the tree level

\[
A(K_{L} \rightarrow \pi^{0} \gamma)_{\text{tree}} = c A(K_{S}^{0} \rightarrow \pi^{0} \gamma) \quad (19)
\]

with \( A(K_{S}^{0} \rightarrow \pi^{0} \gamma) = A(K_{S}^{0} \rightarrow \pi^{0} \gamma) \) and \( c \) the usual CP violation parameter of \( K \rightarrow \pi \) decays \( (|c| = 2.3 \times 10^{-3}) \). In fact, the integrated rate for \( K_{L} \rightarrow \pi^{0} \gamma \) turns out to be dominated by (19). In order to test the chiral prediction for the one-loop amplitude (8) one must therefore perform a cut in \( q^{2} \). From Fig. 2 it can be seen that a cut \( z \geq 0.2 \) makes practically no difference for the characteristic behaviour of the one-loop amplitude. On the other hand,

\[
\frac{\Gamma(K_{L} \rightarrow \pi^{0} \gamma)_{\text{tree}}}{\Gamma(K_{L} \rightarrow \pi^{0} \gamma)_{\text{loop}}} = 2.10^{-4} \quad (20)
\]

so that the amplitude (19) may safely be neglected for \( z \geq 0.2 \). In turn, the accuracy quoted, the branching ratio for \( K_{L} \rightarrow \pi^{0} \gamma \) with a cut \( z \geq 0.2 \) is still given by Eq. (11).

In summary, we have shown that the decay \( K_{L} \rightarrow \pi^{0} \gamma \) is unambiguously calculable at the one-loop level in chiral perturbation theory because of the absence of possible counterterms. Eliminating the CP violating tree level amplitude with a small cut in \( q^{2} \), we find a branching ratio of \( 6.8 \times 10^{-7} \) which should be experimentally accessible in the near future.
Furthermore, the spectrum in the invariant mass of the two photons is predicted to have a very characteristic behaviour. The decay $K_S \rightarrow \pi^0 \gamma \gamma$ is dominated by the pion pole contribution over the whole Dalitz plot because the $\eta$-contribution is here suppressed. The chiral structure of weak vertices can then be tested from a comparison with the predicted $q^2$-spectrum.
