Abstract

It is shown that gauge theories give contributions to neutrinoless double beta decay $[(\beta\beta)_{0\nu}]$ which are not covered by the standard parametrizations. While probably small their existence raises the question of whether the observation of $(\beta\beta)_{0\nu}$ implies the existence of a Majorana mass term for the neutrino. For a "natural" gauge theory we argue that this is indeed the case.
The associated questions of neutrinoless double beta decay (denoted $(\beta\beta)_{0\nu}$) and neutrino mass have again become of general interest. A comprehensive recent discussion is given by Doi et al [1] and a concise summary by Rosen [2].

The classical analysis of the $(\beta\beta)_{0\nu}$ process which of course predated gauge theories by many years, assumed that it arose as a result of neutrino exchange between two effective four fermion vertices. This is shown in modern language in Fig. 1a, which illustrates the process at the quark level. Thus, the parametrization of the $(\beta\beta)_{0\nu}$ process was considered to be given fundamentally by the parametrization of the four fermion single beta decay interaction.

We point out here that the situation is more complicated [3] if the weak interactions are described by a gauge theory. For definiteness we consider $(\beta\beta)_{0\nu}$ in the framework of the standard SU(2) x U(1) gauge theory. Larger gauge groups usually contain SU(2) x U(1) as a subgroup and composite models are usually contrived to also display this symmetry. Thus there is not much loss of generality in doing so.

A rather minimal way [4] to naturally include lepton number violation in the theory is to add to the complex Y=1, I=1/2 Higgs doublet a complex Y=2, I=1 isotriplet $H$:

$$\phi = \left( \begin{array}{c} \phi^+ \\ \phi^0 \end{array} \right) \quad H = \left( \begin{array}{cc} h^+ \\ \frac{1}{\sqrt{2}} h^0 \\ - \frac{1}{\sqrt{2}} \end{array} \right)$$

(1)

The theory need not contain any more than one two-component Weyl neutrino field for each generation [5]. In a natural theory (no special adjustment of parameters) both $\phi^0$ and $h^0$ will develop non-zero vacuum expectation values giving the relations [4]:

$$\langle \phi^0 \rangle \equiv \lambda \quad \langle h^0 \rangle \equiv \frac{v}{\sqrt{2}}$$

$$m^2(W) = \frac{g^2}{4} \left( \lambda^2 + 2\frac{v^2}{\sqrt{2}} \right)$$

$$m^2(Z) = \frac{g^2}{4 \cos^2 \theta_W} \left( \lambda^2 + 4 \frac{v^2}{\sqrt{2}} \right)$$

$$\frac{g_F}{\sqrt{2}} = \frac{g^2}{8 m^2(W)}$$

(2)
in standard notation. The vacuum value $y$ is expected to be small compared to $\lambda$, but the experimental constraints are not very tight [6]. For our purposes it is important to note that the singly charged field $\chi^-$ which is not absorbed by the gauge field is the linear combination

$$\chi^- \simeq h^- + \omega \Phi^- , \quad \omega = -\sqrt{2} \frac{y}{\lambda}$$

where we have assumed $\omega$ to be small. Notice also that the "Yukawa" interaction of $H$ allows a virtual $h^-$ to annihilate into two left handed electron fields ($e^-\bar{e}^\nu$) with strength $m_\nu/y$ ($m_\nu$ is a characteristic neutrino mass). Then there are a variety of diagrams for $(\beta\beta)_\nu$ which involve no virtual neutrino line and hence can not be parametrized by the standard beta decay interaction vertex. These diagrams will require a six-fermion amplitude for their description; the effective Lagrangian will be characterized by a parameter of dimension (mass)$^{-5}$.

A basic new diagram is shown in Fig. 1b. The trilinear $\bar{W}^- W^- h^{++}$ vertex is due to a term in the fundamental Lagrangian:

$$\frac{1}{2} g^2 \langle h^0 \rangle \bar{W}_{\mu} W^\nu \bar{h}^{++} + \text{h.c.}$$

derived from the kinetic term $-\frac{1}{2} \text{Tr} \left[ (D_\mu H)^+ D_\nu H \right]$. The strength of the amplitude for $(\beta\beta)_\nu$ from Fig. 1b is the product of the four trilinear coupling constants and the three propagators:

$$\frac{g^4 m_\nu}{m^2(h^-) m^4(W)}$$

Fig. 1b (5)

Note that the triplet vacuum value has cancelled out of eq. 5. For comparison the "standard" diagram given in Fig. 1a is characterized by a strength [7]

$$\frac{g^4 m_\nu}{m^4(W) \langle p^2 \rangle}$$

Fig. 1a (6)
Here \( \langle p^2 \rangle \) represents a suitable average of the squared four momentum carried by the virtual neutrino, say about \((10 \text{ Mev})^2\). Of course the amplitude for the underlying quark process must be suitably \([1,2]\) folded in the description of the real nucleus. The ratio

\[
\frac{\text{amp for } 1b}{\text{amp for } 1a} = \frac{\langle p^2 \rangle}{m^2(h^-)}
\]

is thus expected to be of order of \(10^{-8}\). Thus the contribution of Fig. 1b seems negligible.

Additional new diagrams involve a tri-linear Higgs interaction (see Fig. 1c). The relevant terms in the Higgs Lagrangian are

\[
c_1 \phi^+(H H^+ H^+) \phi + c_2 T_{\lambda} (H H) T_{\lambda} (H^+ H^+) \\
+ (d \phi^+ H \phi_c + h.c.)
\]

where \( \phi_c \equiv \left( \frac{\phi^o}{\phi^-} \right) \).

Taking into account the mixing between the charged components of the doublet and the triplet Higgs, given by eq. 3, results in the trilinear vertex

\[
g_3 \chi \chi^- h_- h_+ + h. c.
\]

\[
g_3 \propto \sqrt{2} \omega c_i \langle \phi^o \rangle + 2c_2 \langle h^o \rangle - \omega^2 d
\]

The strength parameter associated with Fig. 1c is then

\[
\frac{\omega^2 m_q^2 m_\nu g_3}{\sqrt{2} \lambda^1 m^2(h^-) m^2(\chi^-)} \quad \text{Fig. 1c}
\]

\( (m < 10 \text{ Mev is a light quark mass}). \quad \text{Eq. 10} \)

(\( m < 10 \text{ Mev is a light quark mass}). \quad \text{Eq. 10} \)

involves unknown parameters characterizing the effective Higgs
sector of the theory. Let us first estimate the contribution to eq. 10 coming from the $c_i$ and $c_\omega$ terms. These are dimensionless parameters and can be reasonably expected to be of order unity, at most. Further estimating $m^2(h^-) \approx m^2(\chi^-) \approx \lambda^2$ the ratio of this amplitude to the standard one in eq. 6 is roughly

$$\frac{y^2}{\lambda^2} \frac{m^2_{q} \langle p^2 \rangle}{\lambda^4} \approx \frac{\omega^2}{10^{13}}$$

(11)

which is quite negligible. The contribution to eq. 10 from the $d$ term ( $d$ has dimensions of mass) is potentially more interesting. If one imposes lepton number conservation on the theory $d$ will be zero and there will be no contribution. Then lepton number breaks spontaneously and one has a massless "Majoron"[8]. In such a case $\omega$ will also be very small. However since $\alpha$ does carry a dimension one might regard it as an indicator of a new mass scale [9] and let it remain. Then the ratio of the $d$ contribution to eq. 10 to the standard amplitude eq. 6 is roughly

$$\frac{\omega^3 m^2_{q} \langle p^2 \rangle}{\lambda^4} \frac{d}{\lambda} \approx \frac{\omega^2}{10^{13}} \frac{d}{\lambda}$$

(12)

This indicates that ( even neglecting the suppression due to the $\omega^3$ factor ) $d$ would have to be of the order of the grand unification mass scale for the diagram of Fig. 1c to play an important role.

The presence of the Higgs field $\chi^-$ in the theory also results in new diagrams of the standard form 1a in which one or both of the W's is replaced by a $\chi^-$. These diagrams, which also modify the V-A structure of the single beta decay interaction, are quite small.

Thus we reach the conclusion that for the SU(2)$\times$U(1) theory defined by the Higgs content (1), the effect of the new diagrams is quite small if one considers only mass scales lower than that of grand unification.

One type of neutrinoless diagram which may conceivably be relatively strong without superheavy masses is shown in Fig. 1d. Here a new $Y=-4$ isosinglet Higgs field $\psi^-$ is introduced in addition to the doublet and the triplet. The
virtual $\Psi^-$ decays into two $e_R^+$'s rather than two $e_L^-$'s as in the previous cases. In this case the $\Psi^{++}e_R^+e_R^-$ Yukawa interaction is not proportional to the neutrino mass (as was required previously since the $h^{++}e_L^-e_L^-$ Yukawa term is related by an isospin transformation to the $h^0\nu\nu$ term which generates neutrino mass) and thus may be of order unity [10]. The term in the Higgs Lagrangian which generates the trilinear $\chi^-\chi^-\Psi^{++}$ coupling in Fig. 1d is

$$\phi^+H^+\phi_L\Psi^{++} + h.c.$$  (13)

The amplitude for Fig. 1d would then roughly be of order $\omega^2m_\phi^2y_\Psi^2/2^8$

The ratio of this to the usual amplitude, which is suppressed by a factor of $m_\nu$, is about

$$\frac{\omega^2y^2m_\phi^2|\langle p^2\rangle|}{m_\nu^{1/2}}$$  (14)

This could be comparable to one if $m_\nu$ is exceptionally small! Other models with extra Higgs fields can also boost the new contributions.

To sum up we can say that while neutrinoless decays should really take into account their possible existence, this is because the general structure (as opposed to detailed predictions) of gauge theories seems to be the safest guide to the parametrization of weak interaction amplitudes. It would be desirable to develop criteria [11] based on angular distributions of the decay products for distinguishing these diagrams from the usual ones.

We will conclude this note with a brief discussion of the relation between the $(\beta\beta)_\nu\nu$ process and non-zero neutrino mass. After noticing the existence of neutrinoless diagrams one might be tempted to try to construct models without massive neutrinos and which would still give $(\beta\beta)_\nu\nu$. However such a search would be in vain. For the model based on the Higgs content (1) this result is obvious since eqs. (5) and (10) are proportional to $m_\nu$. It is also true for the model with $\Psi^-\Psi$ : although this model gives an amplitude with no $m_\nu$ factor there is an overall factor of $y=\langle h^0\rangle$. Now in a natural theory $H$ will couple to the basic lepton doublet so that a non-zero value of $y$ will generate a neutrino mass.

Still one might think that a yet more clever
choice of the Higgs representation content could do the job. Rather than attempt an enumeration of all possible Higgs structures we will give a general and yet very simple proof that the existence of $(\beta^\beta)_{\nu\nu}$ implies that the electron neutrino has non-zero mass. Essentially all one needs is to assume that the weak interactions are described by a local gauge theory. In this framework crossing symmetry will hold so the existence of $(\beta^\beta)_{\nu\nu}$ implies a non-zero amplitude for the virtual process $e^+e^- \rightarrow u\bar{u}d\bar{d}J\phi$. This is shown in Fig. 2, where the "black box" may contain any mechanism whatsoever for generating $(\beta^\beta)_{\nu\nu}$. Now any realistic gauge theory will include the ordinary $W$ gauge field interaction with the left-handed electron and neutrino and with the $u$ and $d$ quarks. Using four of these vertices and connecting the lines together as in Fig. 2 shows that we develop an amplitude which gives a non-zero Majorana mass for the electron neutrino.

One might object that some other diagram might precisely cancel [12] Fig. 2 but this would clearly involve fine tuning of parameters and would be unnatural.

The converse question is whether a non-zero neutrino mass implies the existence of $(\beta^\beta)_{\nu\nu}$. If the massive neutrino is of Majorana type, Fig. 1a shows that $(\beta^\beta)_{\nu\nu}$ will occur. If the neutrino is of Dirac type the $(\beta^\beta)_{\nu\nu}$ will not occur [13]. One may, however, exclude the possibility of neutrinos being of Dirac type if one postulates a "strong-naturality" in which no global conservation laws are assumed "a priori". In such a case massive neutrinos will be [14] of Majorana type.

Fig. 1 Diagrams for neutrinoless double beta decay in an SU(2) x U(1) gauge theory. The standard diagram is Fig. 1a. It is the only one which contains a virtual neutrino (of four momentum p). d and u are the "down" and "up" quarks.

Fig. 2 Diagram showing how any neutrinoless double beta decay process induces a $\nu_e$ to $\nu_e$ transition, that is, an effective Majorana mass term.
Footnotes and references

[3] After the work described in this paper was completed we received a preprint (City University of New York CCNY-HEP-81/9, September 81, by R. N. Mohapatra and J. D. Vergados) which also points out the need for the intrinsic six-fermion interactions. However, the discussions of the two papers are somewhat different.

[4] See for example

[5] For simplicity we will consider the theory to contain only one generation.

[7] The lepton number violating Majorana neutrino propagator in Fig. 1a is responsible for the factor $m_\nu/\langle p^2 \rangle$.

[8] See for example
Gelmini and Roncadelli and Georgi et al., ref. 4 above.

[10] If the leptonic Yukawa coupling constant in Fig. 1c is of order unity, $\psi^c$ will be approximately $m_\nu$ and one will have enormous suppression of this diagram due to the factor $\omega^2$ in eq. 1c.

[12] Also one would have to cancel all variations on the basic Fig. 2, which is extremely unlikely. For example, a photon may be exchanged between each u and d line.

[13] A Dirac neutrino can be conceived of as a pair of mass-degenerate Majorana neutrinos with opposite CP assignments. As
pointed out by Wolfenstein [Carnegie-Mellon preprint CMU-3066-180], their contributions to the $(\mu\nu)_{\nu\bar{\nu}}$ rate cancel due to their relative CP phase. With several Majorana neutrinos with different CP eigenvalues the neutrinoless diagrams discussed here may not be entirely negligible.

[14] See, for example, the discussion in section 1 of the first of refs. 4 above.
